

climate model integration

Integration of Metamodels into FutMon

FutMon final Workshop 21 June 2011

Konstantin Olschofsky

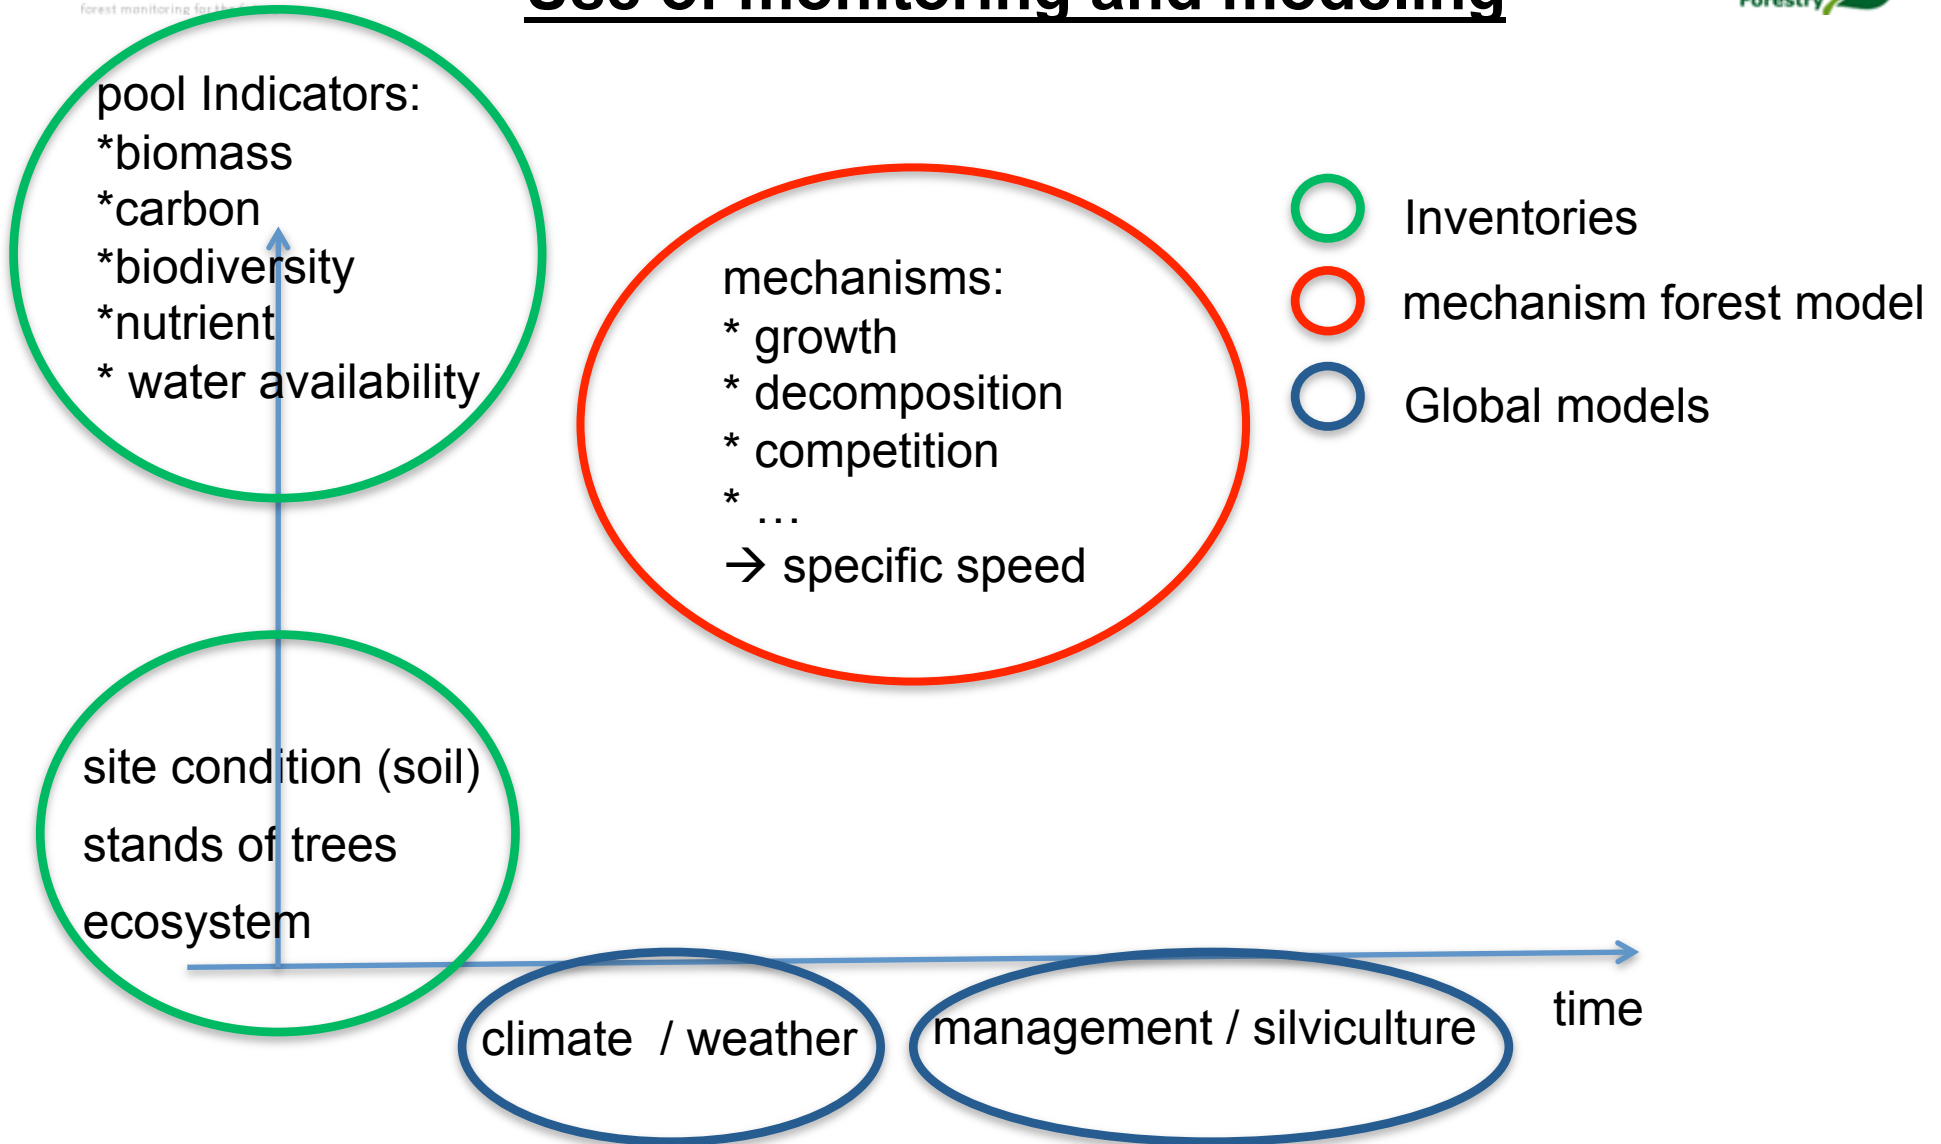

FUTMON
forest monitoring for the future

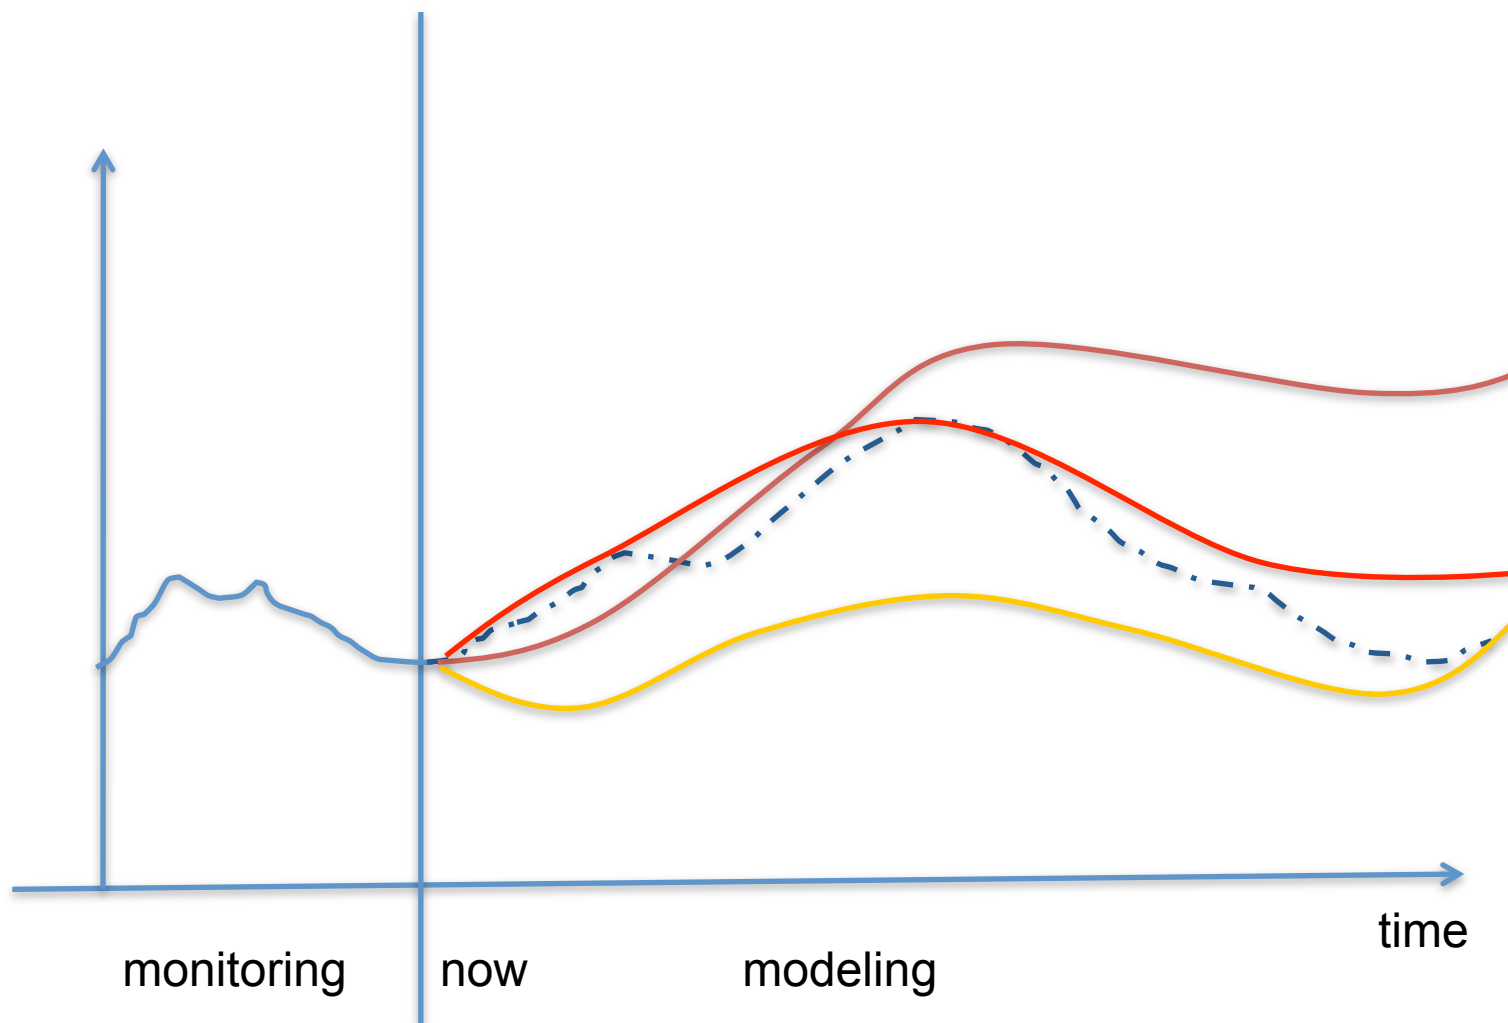

climate model integration

Use of monitoring and modeling

Scenarios versus Predictions

climate model integration

Aim of modeling and benefit from FutMon

- calibration and adaptation of local models
- estimation of growth and trends for GHG reporting
- investigation of different forest management strategies
- management adaptation strategies
- estimation of risks and adaptation mechanism
- verification of sustainability
- combination with other data sources for extrapolation

→ FutMon provides the basic data for pan European modeling applications, which are able to answer upcoming social questions.

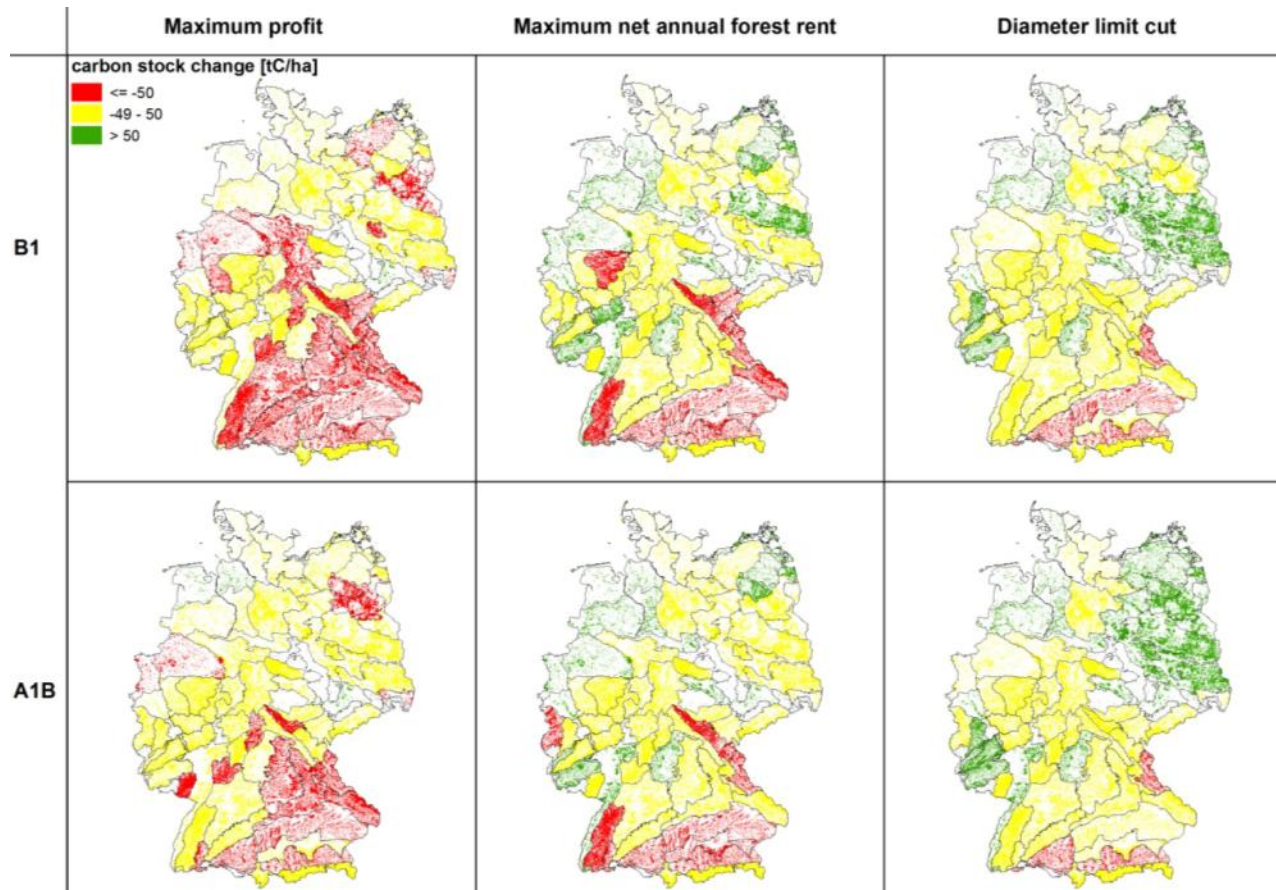

FUTMON
forest monitoring for the future

climate model integration

Interaction of future climate and human needs

[Köhl et al. 2010 <http://www.cbmjournals.com/content/5/1/8>]

maximising profit

- soil
- litter
- below ground
- above ground
- wood products from 2000
- wood products up to 2000

maximising net yield

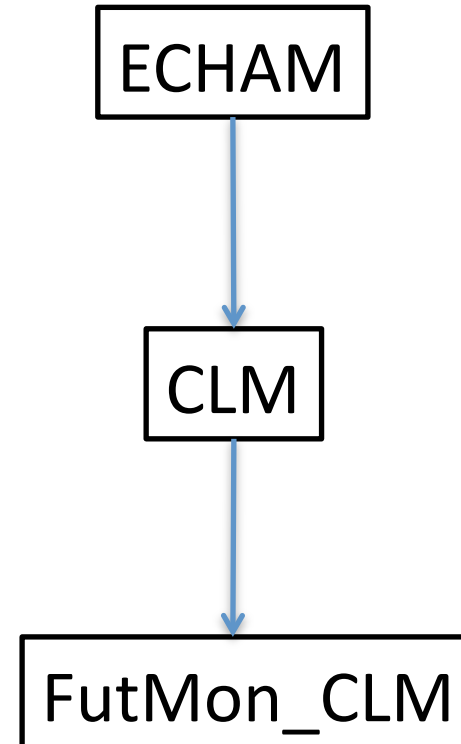

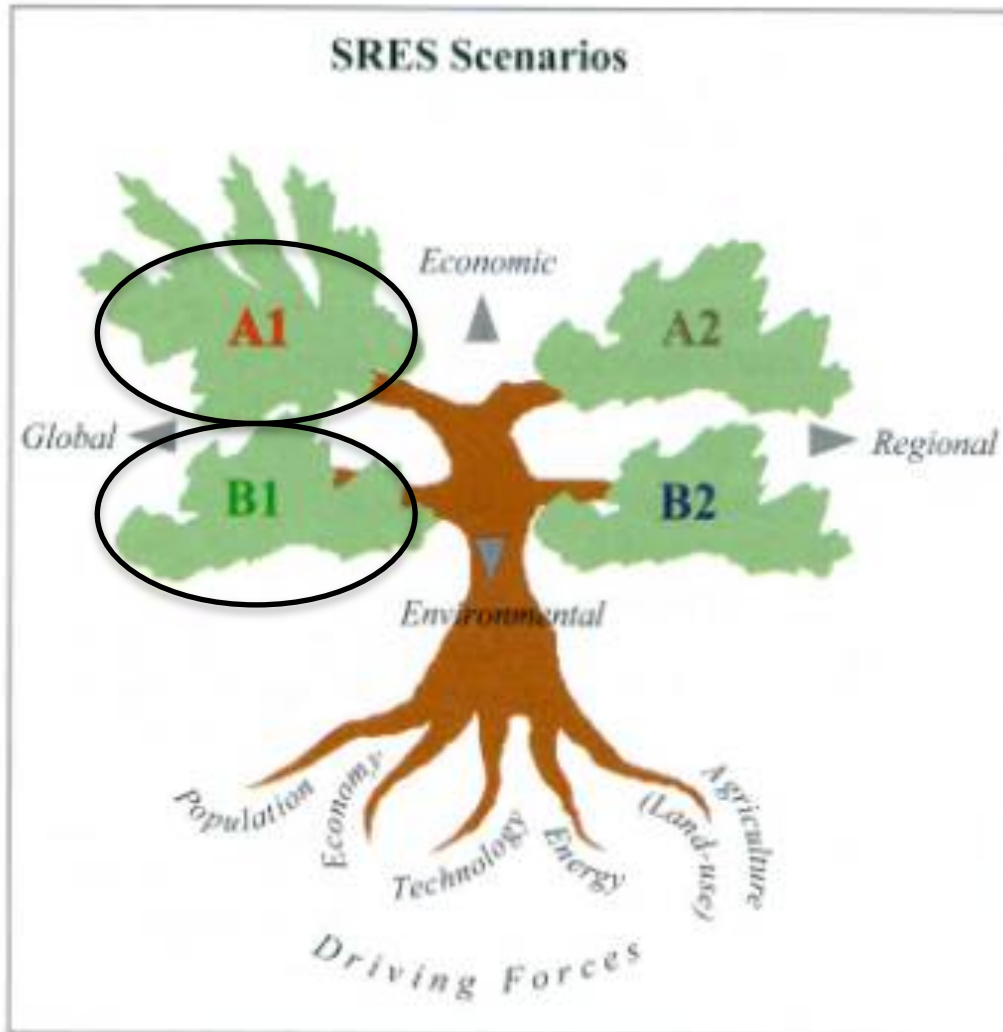

- soil
- litter
- below ground
- above ground
- wood products from 2000
- wood products up to 2000

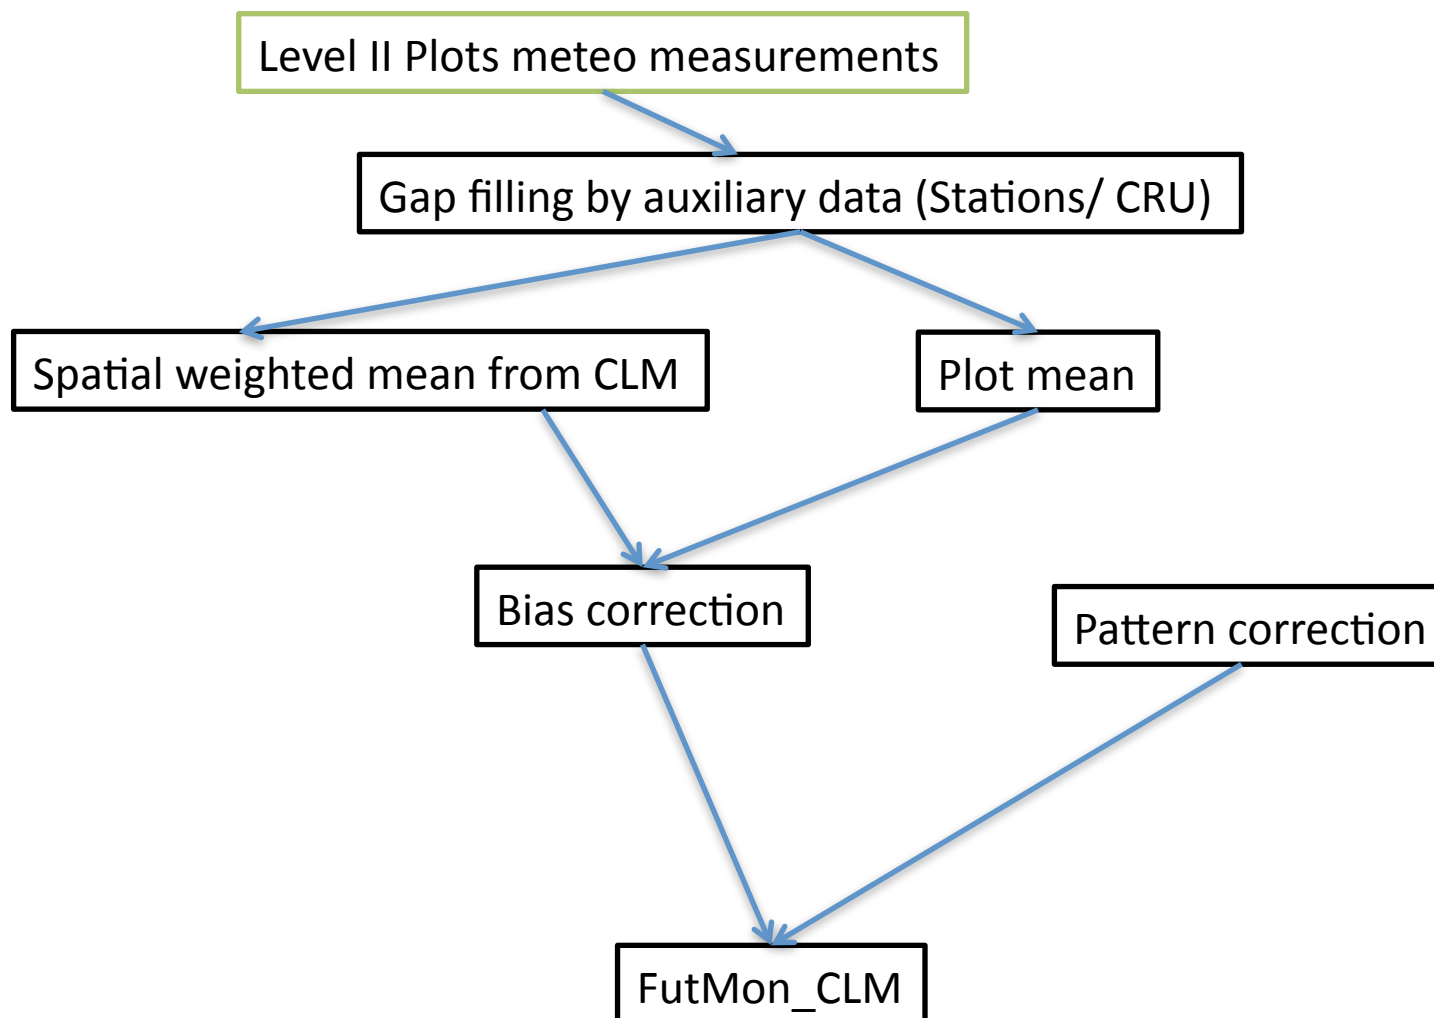

FUTMON
forest monitoring for the future

Climate models:

climate model integration

Methodology of regionalization :

Results:

- meteo regionalization is possible
- Level II basis for transfer to Level 1, NFI
- meteo data is one main factor for extrapolation
- forest sites having specific local climate
- no general trend was observed, regional approaches are needed

climate model integration

Outcome and findings:

- Integration of climate data allows modeling of scenarios
- FutMon results can be used to facilitate international reporting needs and forest management decisions
- Climate data can be now easily integrated, but the needs for scenarios on future needs of the society on forest should be defined to support decision processes.
